# From Dashboards to Decisions: Predictive and Prescriptive Analytics for Live Games

Live game teams do not need more data for its own sake. They need operational intelligence that helps them act faster, reduce player impact, and make better decisions during incidents, launches, and live events.

---

## IN THIS ARTICLE

- › The analytics maturity curve
  - › Predictive analytics: anticipate operational risk
  - › Prescriptive analytics: turn signals into action
  - › Why automation should not be the first goal
  - › The right operating model for live games
- 

## CORE ARGUMENT

### **Operational analytics only matters when it improves decisions.**

Most live game teams already have dashboards. They already collect metrics. They already know how to look at error rates, latency, CCU, infrastructure health, deployment status, matchmaking behavior, and service availability.

The problem is not always lack of data. The problem is turning operational signals into the right action before player impact grows.

**Predictive analytics helps teams anticipate risk. Prescriptive analytics helps teams choose and execute the right response.**

---

## ANALYTICS MATURITY

### **The maturity curve should lead to better operational control.**

The useful progression is not from data to decoration. It is from visibility to decision-making to controlled action.

<b>Level 1 · Descriptive</b>	What happened? — API errors increased after a deployment.
<b>Level 2 · Diagnostic</b>	Why did it happen? — The error rate is tied to a matchmaking dependency.
<b>Level 3 · Predictive</b>	What is likely to happen next? — CCU trends suggest regional capacity pressure within the next window.
<b>Level 4 · Prescriptive</b>	What should we do? — Trigger an approved runbook, adjust capacity, notify the right team, and validate recovery.

## PREDICTIVE ANALYTICS

### Anticipate operational risk before it becomes player impact.

Predictive analytics is useful when it helps the team see pressure forming before it becomes an incident. For live games, that means more than forecasting abstract trends.

It means identifying early warning signals in the operational environment: capacity pressure, regional latency, abnormal packet loss, rising backend errors, payment friction, authentication instability, matchmaking degradation, or deployment patterns that historically created issues.

- Forecast CCU spikes before capacity pressure becomes visible to players.
- Identify backend degradation before support reports start rising.
- Detect abnormal latency or packet-loss patterns by region.
- Spot deployment risk based on prior incident patterns.
- Recognize early warning signals before live events.
- Prioritize signals based on likely player impact.

#### Predictive analytics

The system helps the team understand what is likely to happen if current signals continue.

- Forecasts operational pressure
- Detects abnormal patterns earlier
- Surfaces likely risk areas
- Improves readiness before incidents
- Supports proactive operational planning

#### Prescriptive analytics

The system helps the team decide what action should happen next, with the right level of control.

- Recommends the relevant runbook
- Classifies severity and likely impact
- Suggests escalation or ownership path
- Recommends rollback or capacity action
- Supports recovery validation and reporting

**PRESCRIPTIVE ANALYTICS**

**Turn signals into action without pretending everything should be automated.**

Prescriptive analytics is often described as the point where systems automatically decide and act. That framing is too simplistic for live GameOps.

In live games, full automation is not always the safest or most credible objective. The stronger model is controlled operational decision support: recommended actions, approved runbooks, severity classification, routing, rollback guidance, capacity recommendations, and recovery validation.

Some actions can be automated. Others should be human-verified. The maturity is knowing the difference.

**Bad automation scales bad assumptions. Before automating response, teams need clean telemetry, trusted thresholds, validated runbooks, clear ownership, and incident history.**

**ZUMIDIAN OPERATING MODEL**

**Human-verified operational intelligence connects signal to response.**

Zumidian positions analytics as a bridge between telemetry and operational execution. The goal is not more charts. The goal is faster qualified action.

<b>Telemetry</b>	Signals from infrastructure, services, network, deployments, and player-impact indicators.
<b>Context</b>	Dashboards, thresholds, patterns, historical incidents, and operational relevance.
<b>Recommendation</b>	Suggested runbook, severity, ownership path, mitigation action, or validation step.
<b>Execution</b>	Runbook-driven response, recovery verification, reporting, and improvement loop.

## PRACTICAL DECISION MODEL

## Which analytics model fits your current operations maturity?

Not every studio should try to jump to prescriptive automation. The right next step depends on the maturity of the telemetry, runbooks, thresholds, incident history, and team ownership model.

<b>You have dashboards but inconsistent action</b>	Diagnostic analytics plus operational runbooks
<b>You have recurring incidents and known patterns</b>	Predictive analytics to identify risk earlier
<b>You have stable runbooks and trusted thresholds</b>	Prescriptive recommendations and guided response
<b>You have mature automation and low-risk actions</b>	Controlled automation with guardrails
<b>You have launch or live-event risk</b>	Human-verified recommendations plus 24/7 coverage

## OPERATIONAL ANALYTICS

## The point is not better dashboards. The point is better operational decisions.

<b>Earlier signal</b>	Identify abnormal patterns before they become broader player-impact issues.
<b>Clearer action</b>	Connect signals to runbooks, ownership, severity, mitigation, and validation steps.
<b>Faster recovery</b>	Reduce time between detection, qualification, response, and verified recovery.

---

---

**BOTTOM LINE****Analytics should reduce operational uncertainty.**

Predictive analytics helps live game teams see risk forming. Prescriptive analytics helps teams decide what to do about it.

But neither creates value if the organization cannot act. The strongest analytics model connects signal, context, ownership, runbook execution, and recovery validation.

For live games, operational analytics should not be judged by the number of dashboards created. It should be judged by whether it helps teams act faster, reduce player impact, and improve the operating model over time.

**Are your analytics helping your team act faster, or just producing more dashboards?**

Schedule a Game Operations Review to assess your operational visibility, incident response model, dashboard maturity, runbook readiness, and decision path from signal to recovery.
